

FAST FOOD ANALYSIS

Data Science · Mr. Merrick · December 3, 2025

Overview

Using the **Fast Food Nutrition** dataset (available on Kaggle at <https://www.kaggle.com/datasets/ulrikthygepedersen/fastfood-nutrition/>), conduct a light exploratory analysis in **R**.

Guiding Questions

Q1. Summarize the dataset.

Report the number of rows, columns, and restaurants. Compute basic summaries for key variables like **calories**, **total_fat**, and **sodium**. Show the distribution of calories (e.g., histogram) and comment on what counts as a “small”, “medium”, and “large” item in this dataset.

Q2. Visualize nutrition distributions.

Make one or more plots showing the distributions of variables such as **calories**, **total_fat**, **sugar**, and **protein**. You could use separate histograms, density plots, or a faceted plot. Briefly compare which nutrients appear most skewed and which have the widest spread.

Q3. Connect to your daily energy needs (TDEE).

Use an online TDEE calculator (e.g., <https://www.calculator.net/tdee-calculator.html>) or a value given by your instructor to estimate your personal **TDEE** (Total Daily Energy Expenditure) in kcal. Create a new variable that gives the **percent of your daily calories** each item represents:

$$\text{cal_pct_day} = \frac{\text{calories}}{\text{TDEE}} \times 100.$$

Show a table or plot of the items that make up at least 25% of your daily calories and comment on whether they seem “worth it”.

Q4. Sodium and daily limits.

Assume a recommended daily sodium limit of 2300 mg (or another value your instructor specifies). Create a new variable for the **percent of daily sodium** each item contains:

$$\text{sodium_pct_day} = \frac{\text{sodium}}{2300} \times 100.$$

Make a plot or table highlighting items that exceed 50% and 100% of this limit, and briefly discuss your findings.

Q5. How do restaurants compare?

Group by **restaurant** and compute summaries such as average calories, average **total_fat**, and average **sodium** per item. Compare at least two restaurants (e.g., McDonalds vs Subway) on these metrics. Include a small table and at least one plot (e.g., bar chart of average calories or fat by restaurant) and interpret key differences.

Q6. Can fat predict calories? (Linear regression)

Investigate the relationship between **total_fat** and **calories**. Make a scatter plot with **total_fat** on the x-axis and **calories** on the y-axis, add a linear trend line, and fit the regression model:

$$\text{calories} \sim \text{total_fat}.$$

Report the correlation, the slope (how many extra calories per gram of fat), and comment on how well fat alone explains calories.

Dataset Description and Citation

The dataset includes information for menu items from several fast food chains: restaurant name, item name, calories, calories from fat, fat grams, carbohydrates, sugar, protein, sodium, and certain vitamins.
